

EECS 370

Set-associative Caches

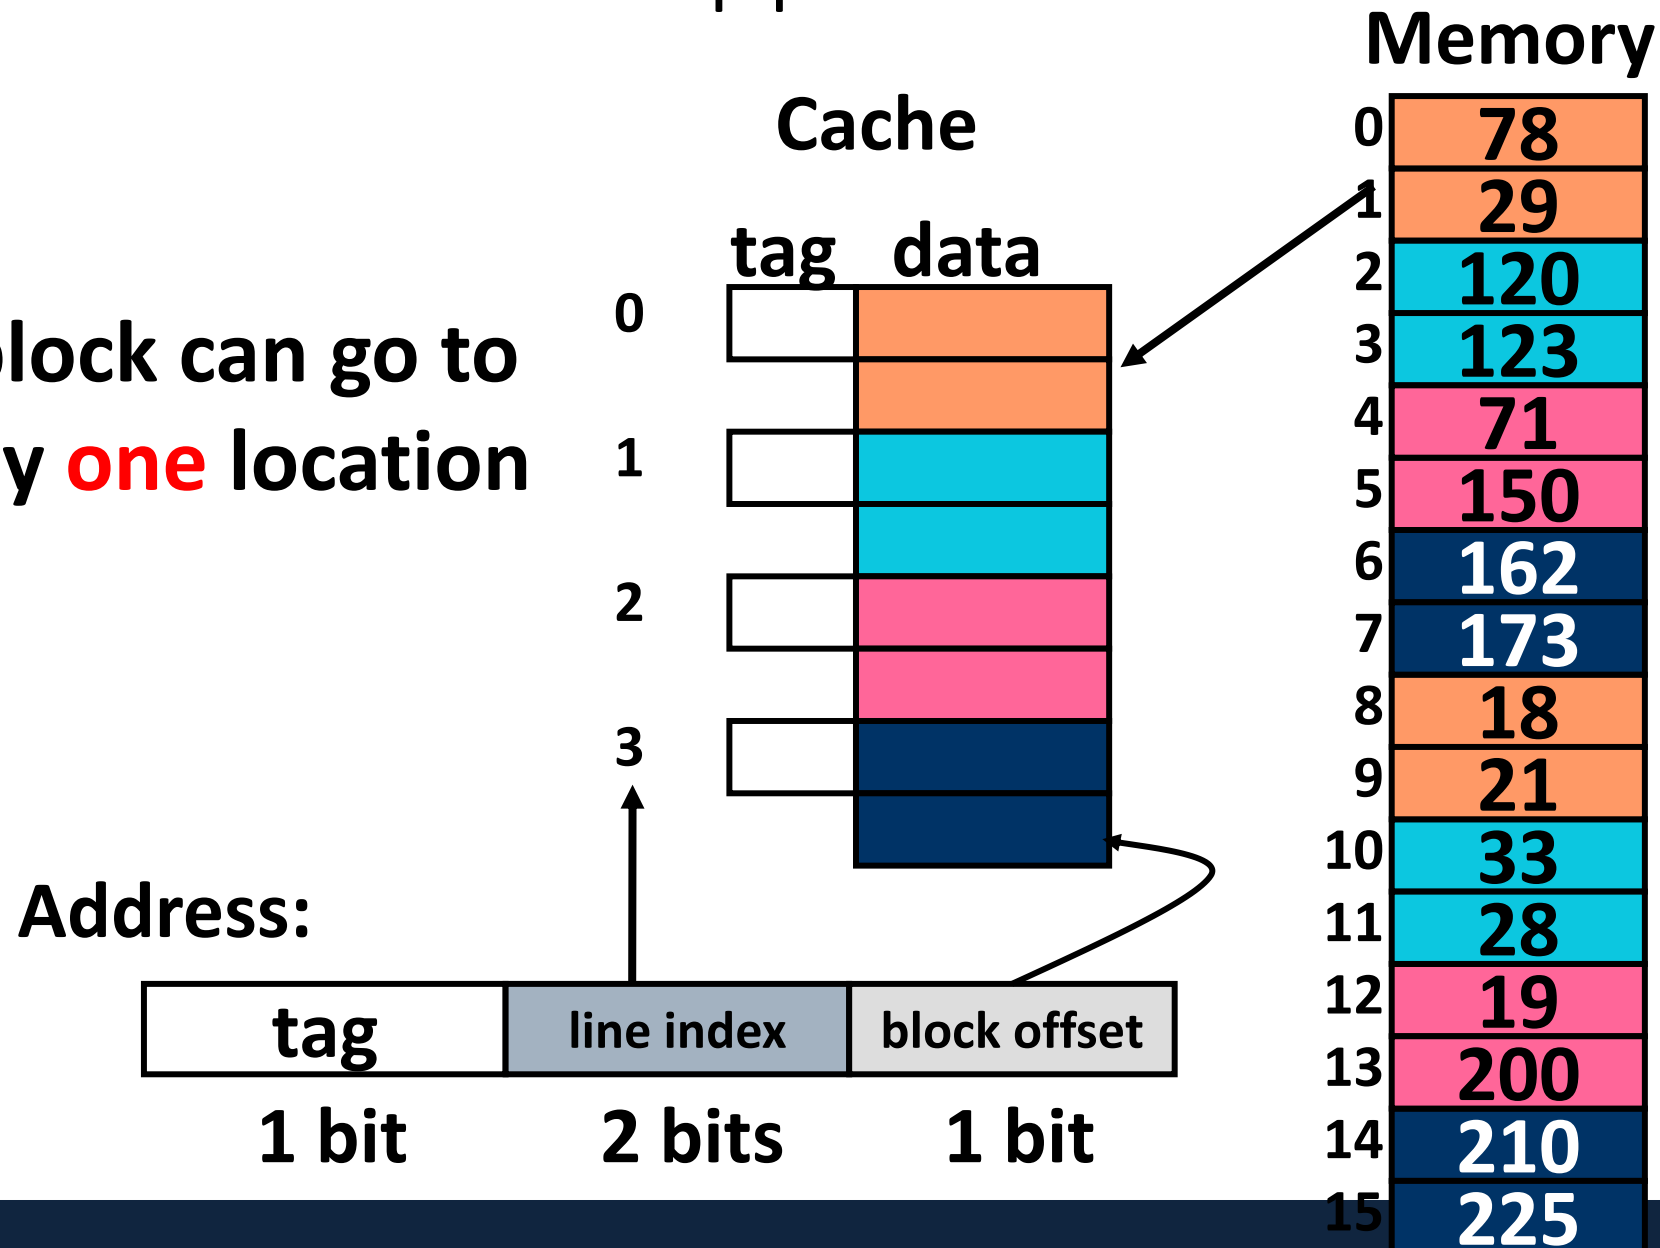

Announcements

- Project 3
 - Checkpoint due today
 - Full submission due next Thursday
- HW 3
 - Due week from Monday (1.5 weeks)
 - Everything relevant has been covered in lecture
- Labs
 - No lab this Friday / next Monday (no prelab either)
 - Extra OH for P3 available instead (see calendar)

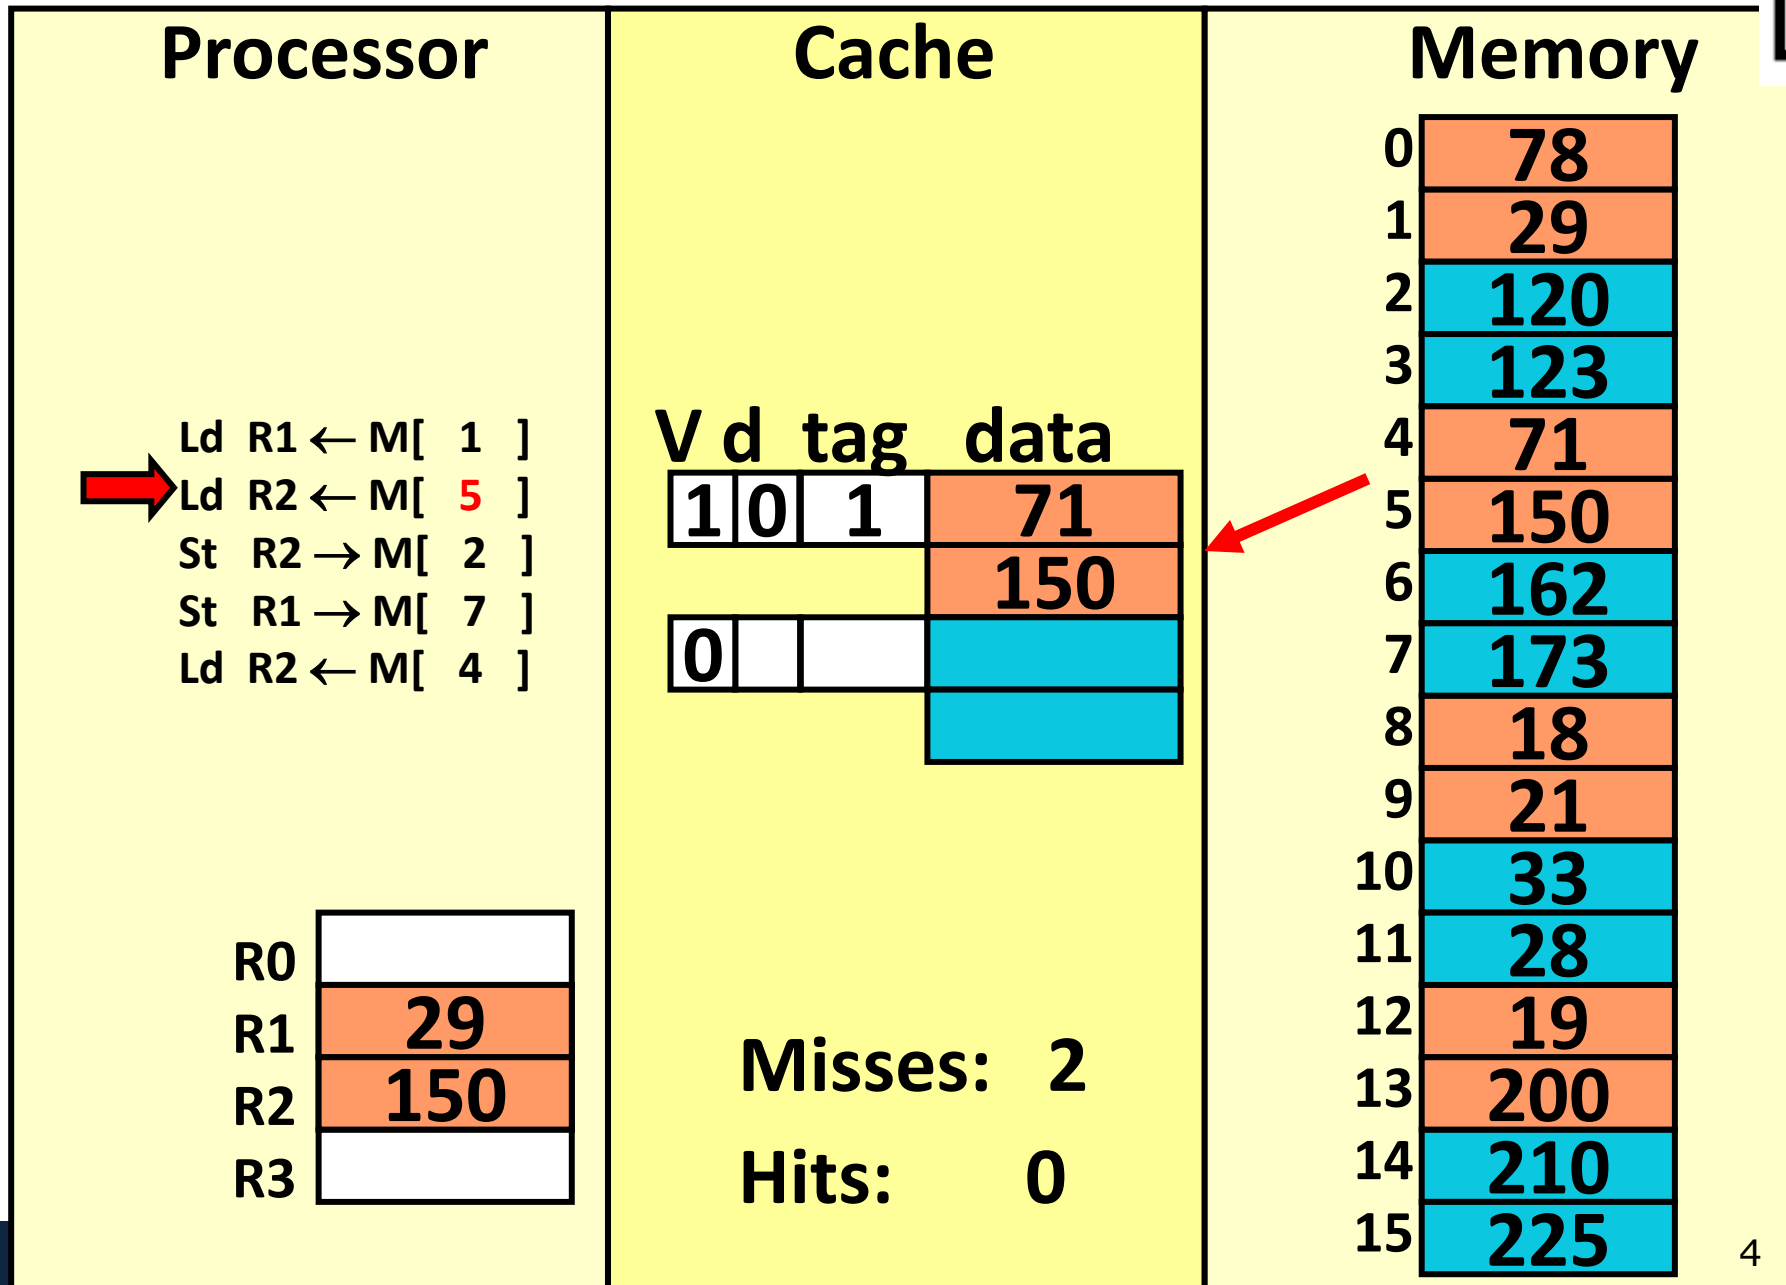

Reminder: Direct Mapped Caches

A block can go to only **one** location

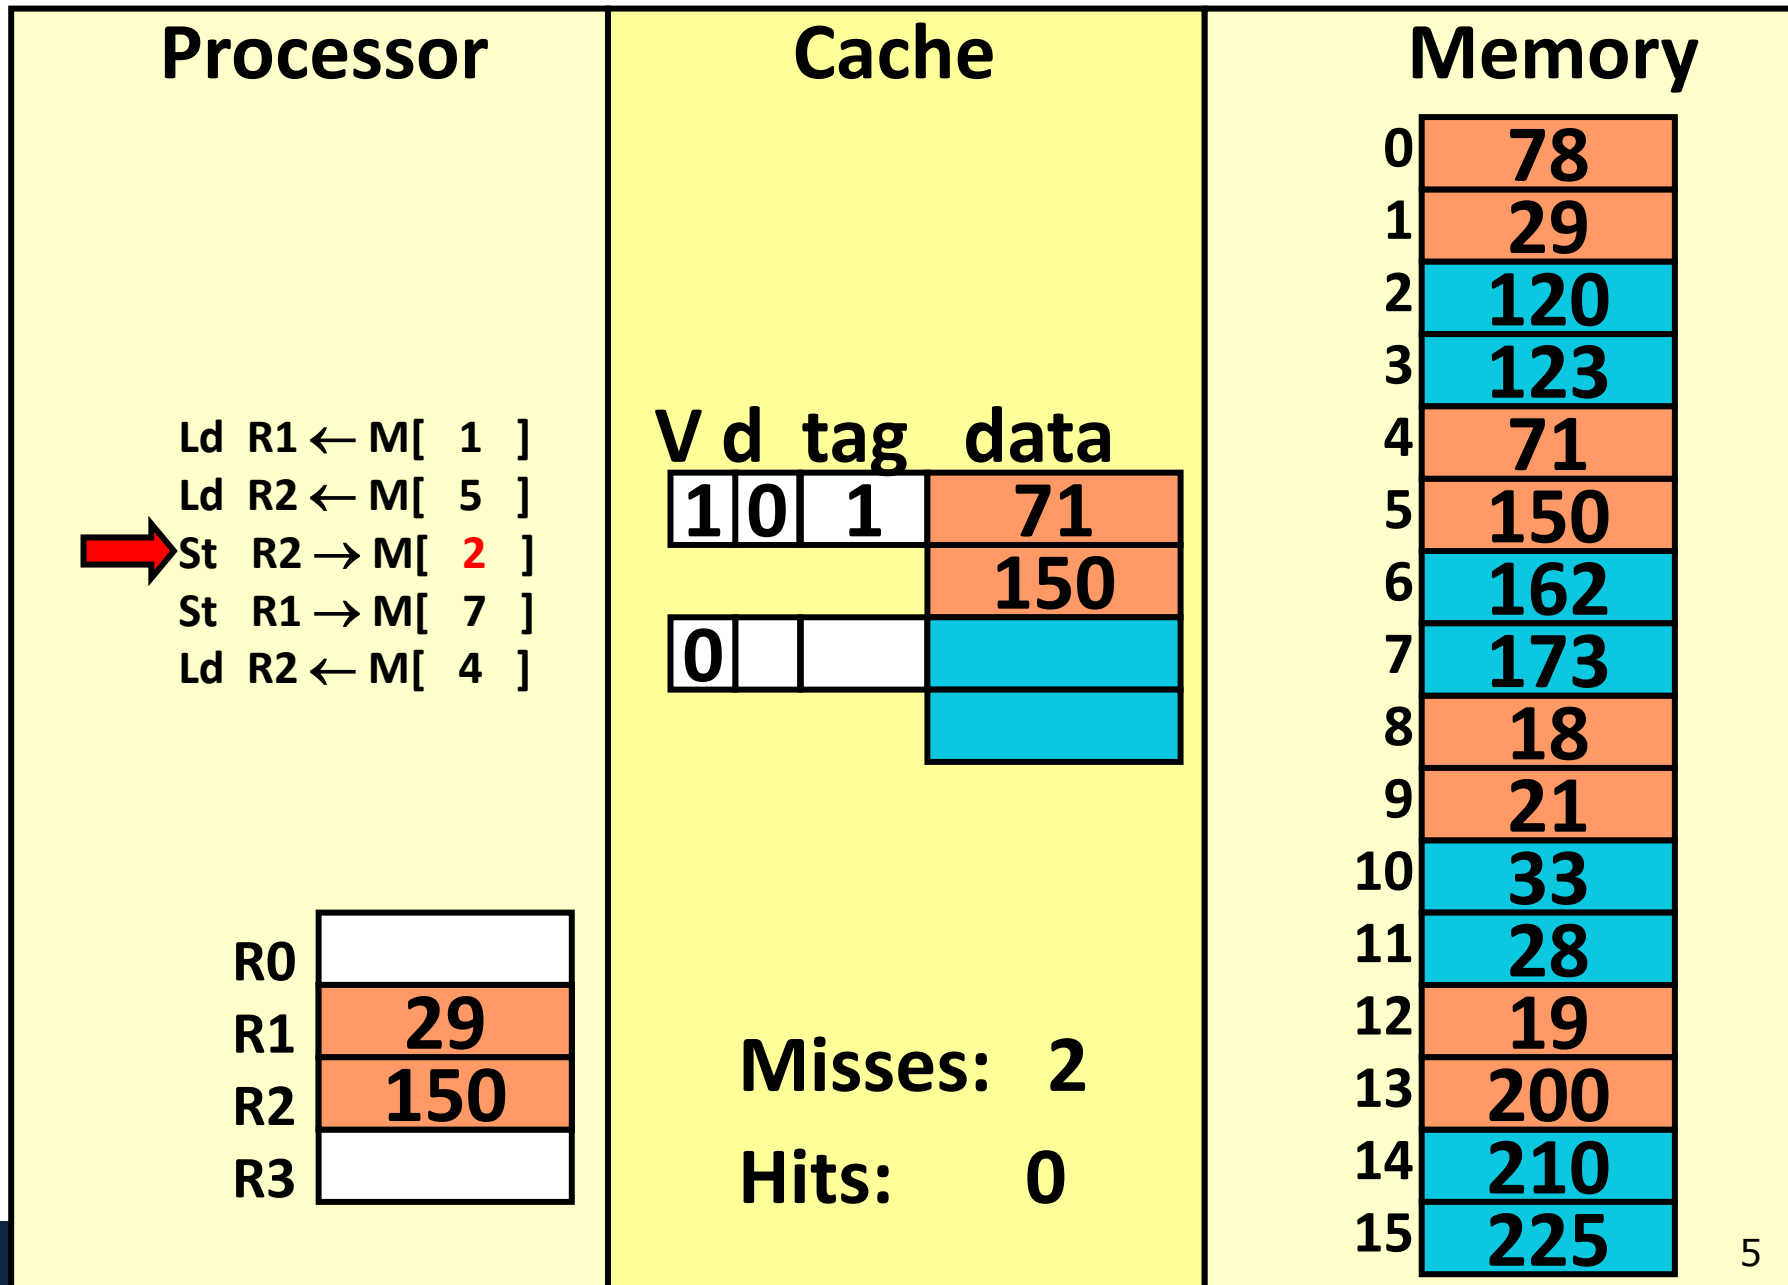

Direct-mapped (REF 2)

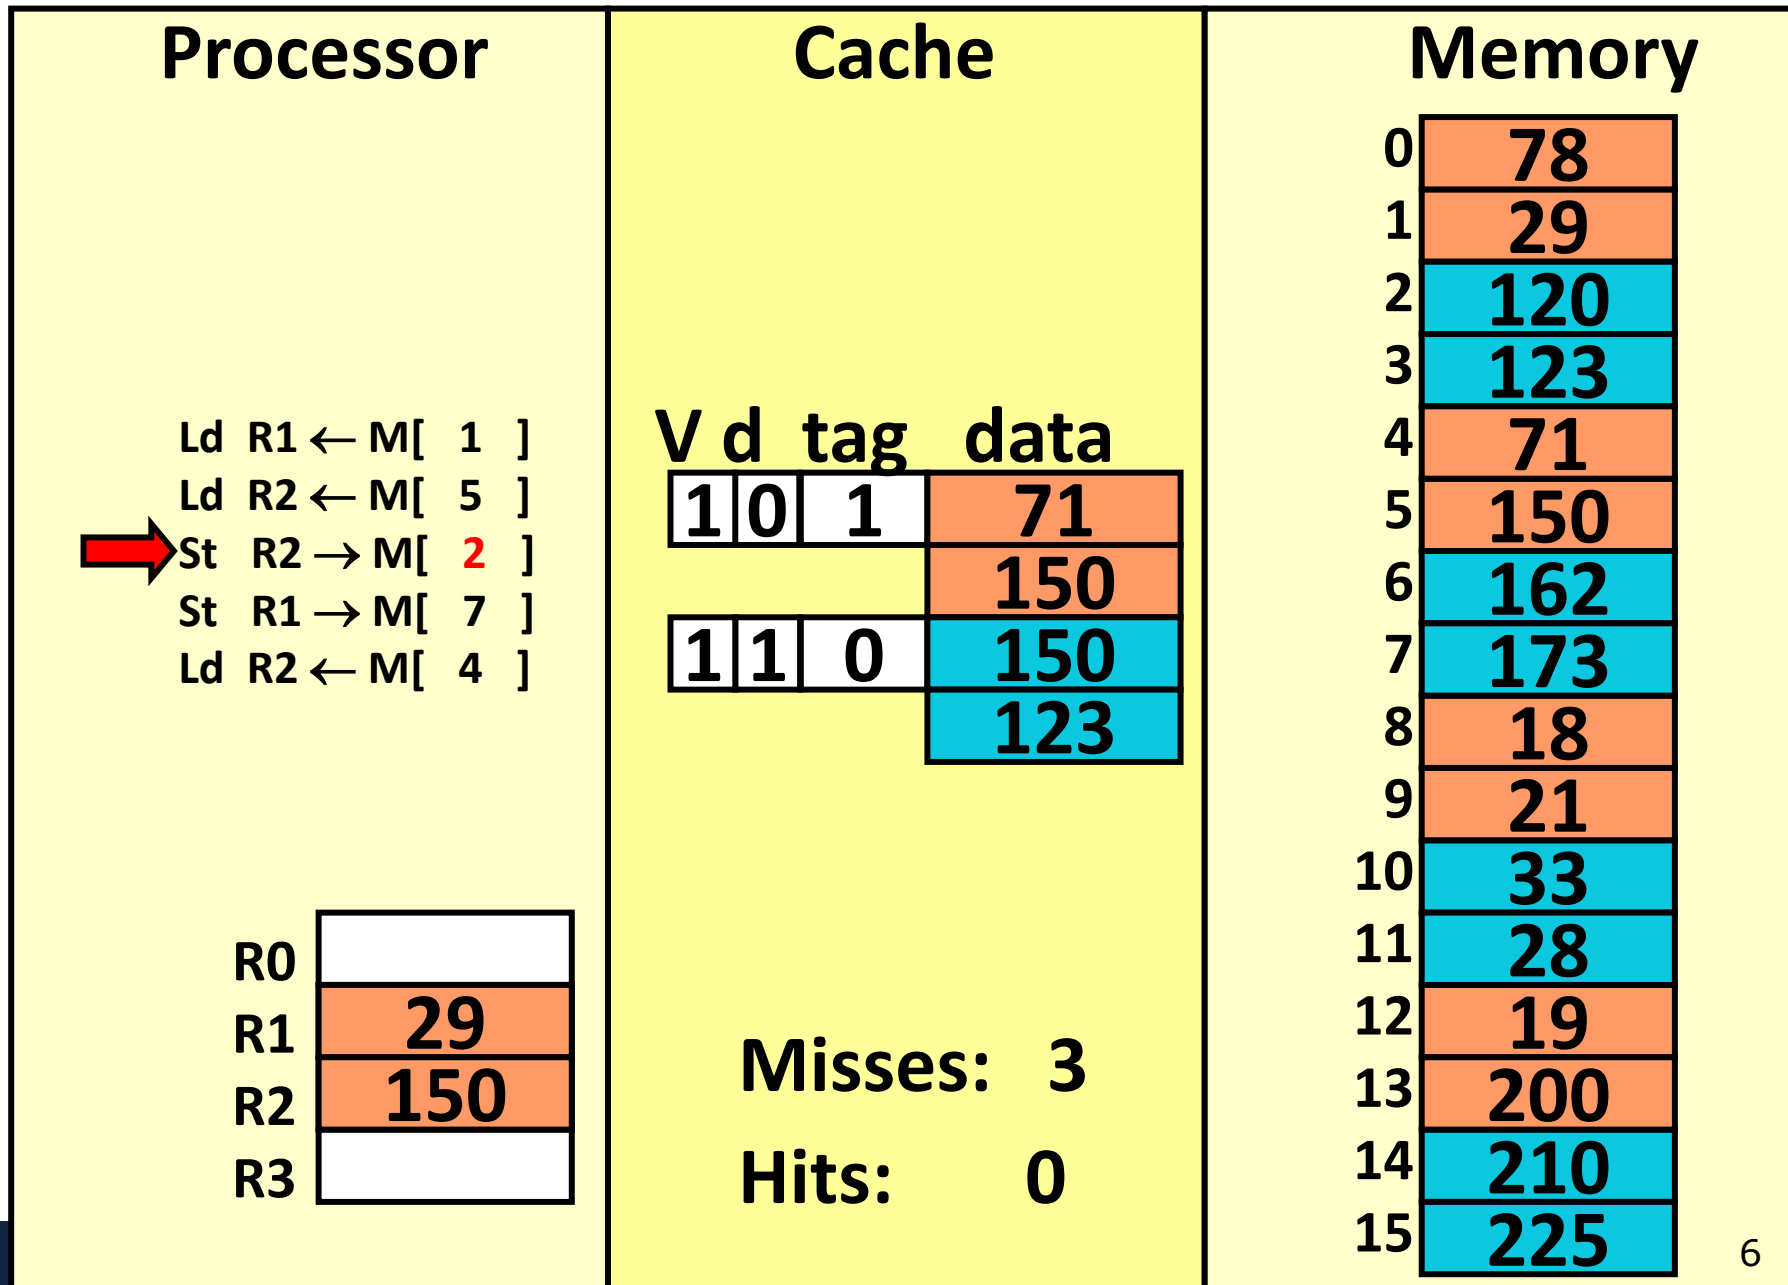

Poll: Complete the last few instructions yourself

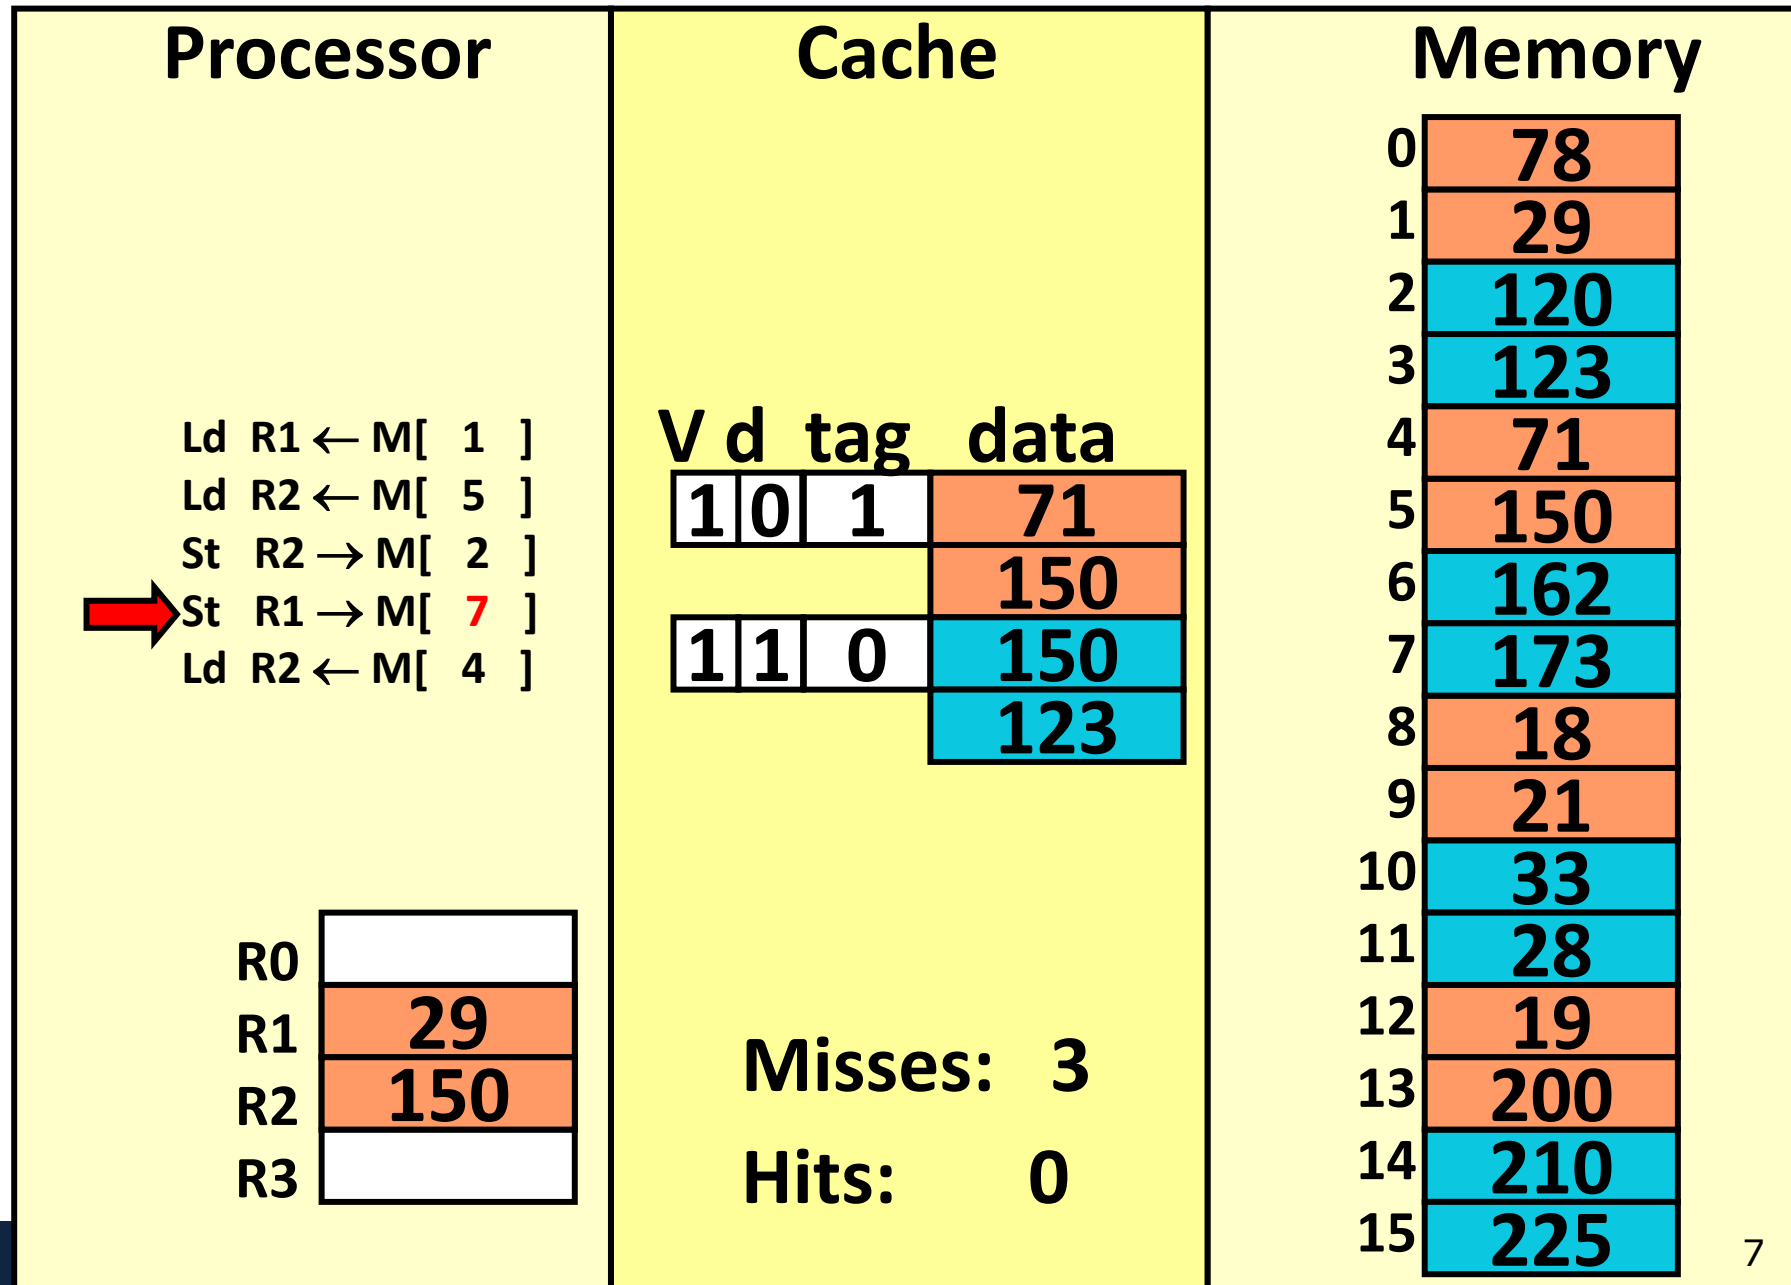

Direct-mapped (REF 3)

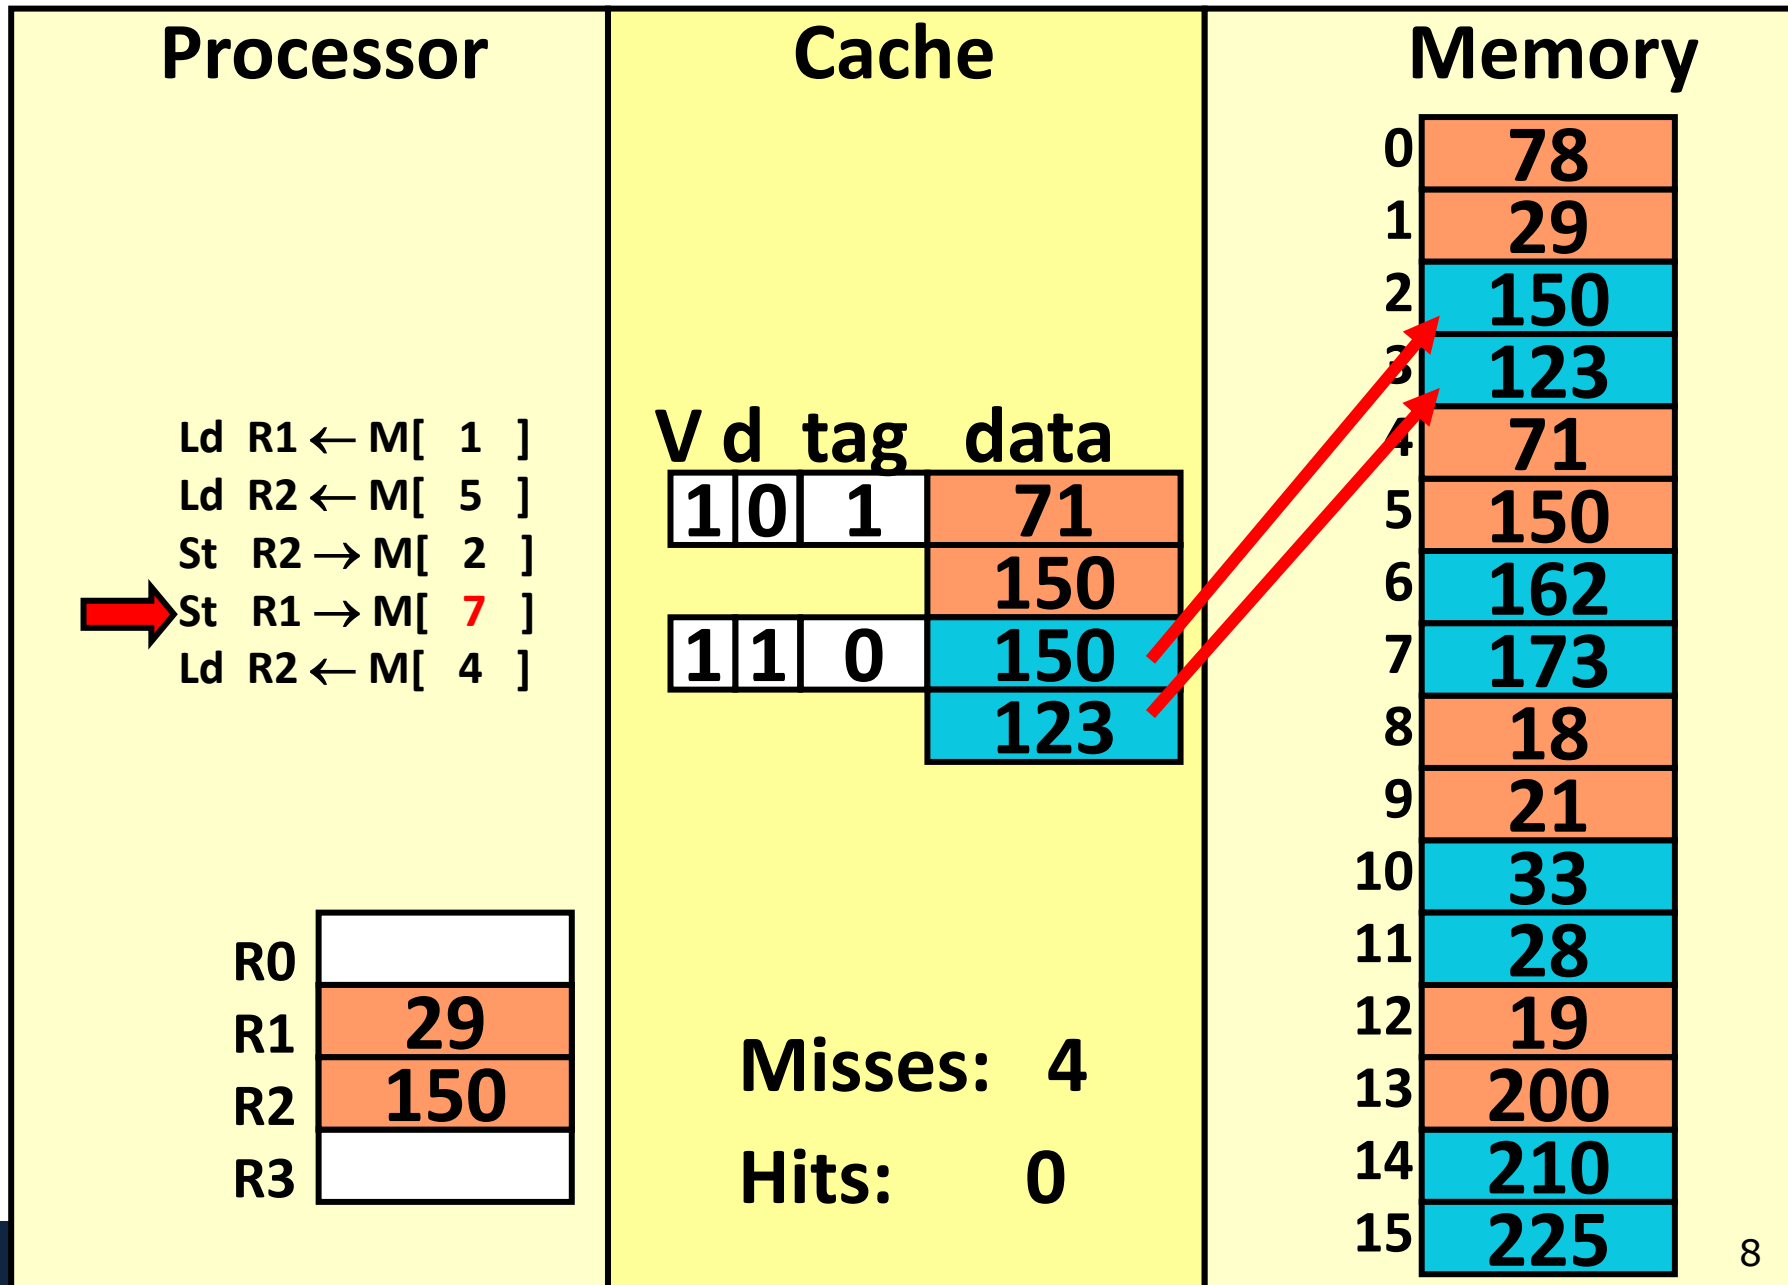

Direct-mapped (REF 3)

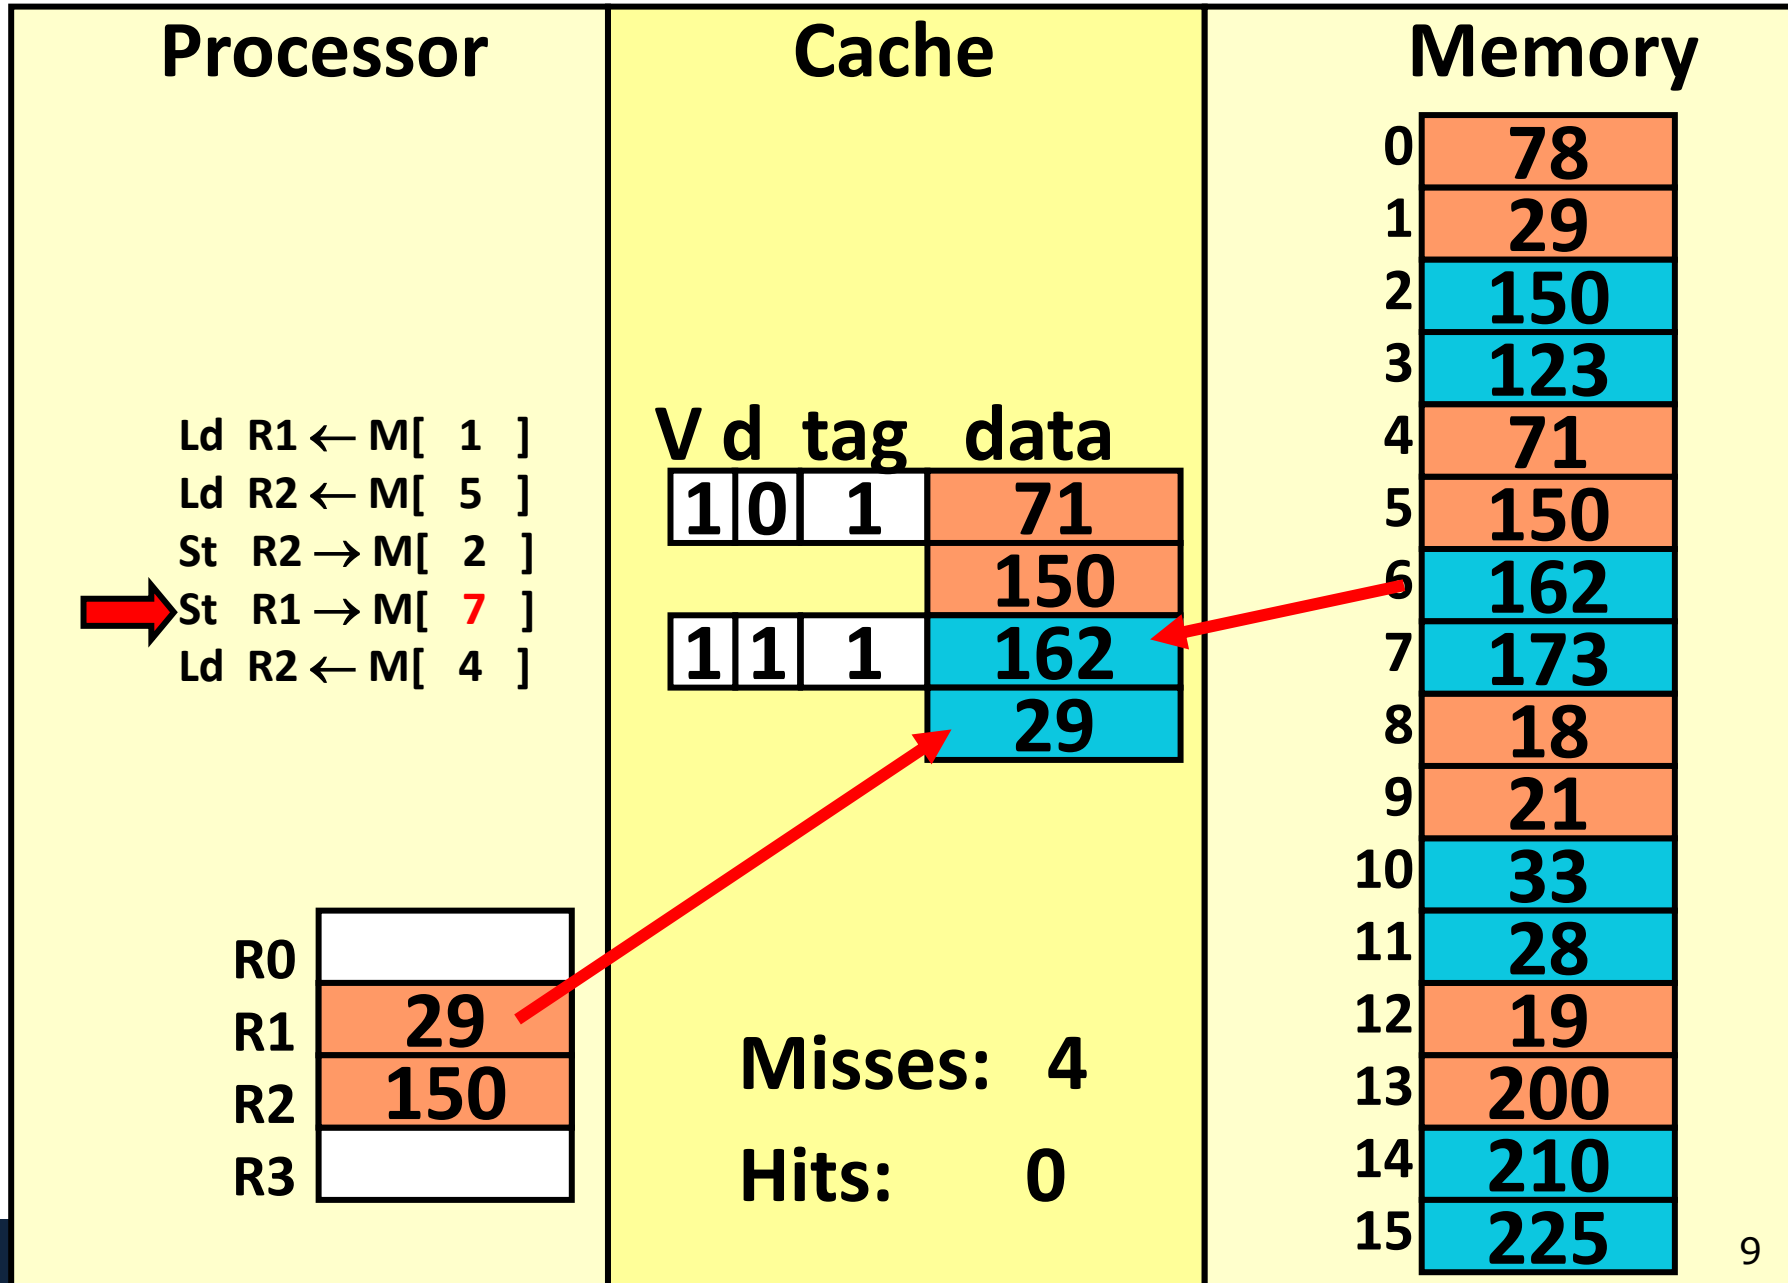

Direct-mapped (REF 4)

Class Problem—Storage overhead

- Consider the following cache:

32-bit memory addresses, byte addressable, 64KB cache

64B cache block size, write-allocate, write-back, *fully associative*

This cache will need 512 kilobits for the data area (64 kilobytes times 8 bits per byte). Note that in this context, 1 kilobyte = 1024 bytes (NOT 1000 bytes!) Besides the actual cached data, this cache will need other storage. Consider tags, valid bits, dirty bits, bits to keep track of LRU, and anything else that you think is necessary.

- How many additional bits (not counting the data) will be needed to implement this cache ?

Class Problem—Storage overhead

- Consider the following cache:
32-bit memory addresses, byte addressable, 64KB cache
64B cache block size, write-allocate, write-back, *fully associative*

This cache will need 512 kilobits for the data area (64 kilobytes times 8 bits per byte). Note that in this context, 1 kilobyte = 1024 bytes (NOT 1000 bytes!) Besides the actual cached data, this cache will need other storage. Consider tags, valid bits, dirty bits, bits to keep track of LRU, and anything else that you think is necessary.

- How many additional bits (not counting the data) will be needed to implement this cache ?

Tag bits = $32 - \log(64) = 26$ bits

#lines = $64\text{KB}/64\text{B} = 1024$

LRU = $\log(1024) = 10$ bits

1 valid bit, 1 dirty bit

38 bits per line * 1024 lines = 38 kilobits

Extra Class Problem—Analyze performance

- Suppose that accessing a cache takes 10ns while accessing main memory in case of cache-miss takes 100ns. What is the average memory access time if the cache hit rate is 97%?
- To improve performance, the cache size is increased. It is determined that this will increase the hit rate by 1%, but it will also increase the time for accessing the cache by 2ns. Will this improve the overall average memory access time?

Class Problem—Analyze performance

- Suppose that accessing a cache takes 10ns while accessing main memory in case of cache-miss takes 100ns. What is the average memory access time if the cache hit rate is 97%?

$$AMAT = 10 + (1 - 0.97) * 100 = 13 \text{ ns}$$

- To improve performance, the cache size is increased. It is determined that this will increase the hit rate by 1%, but it will also increase the time for accessing the cache by 2ns. Will this improve the overall average memory access time?

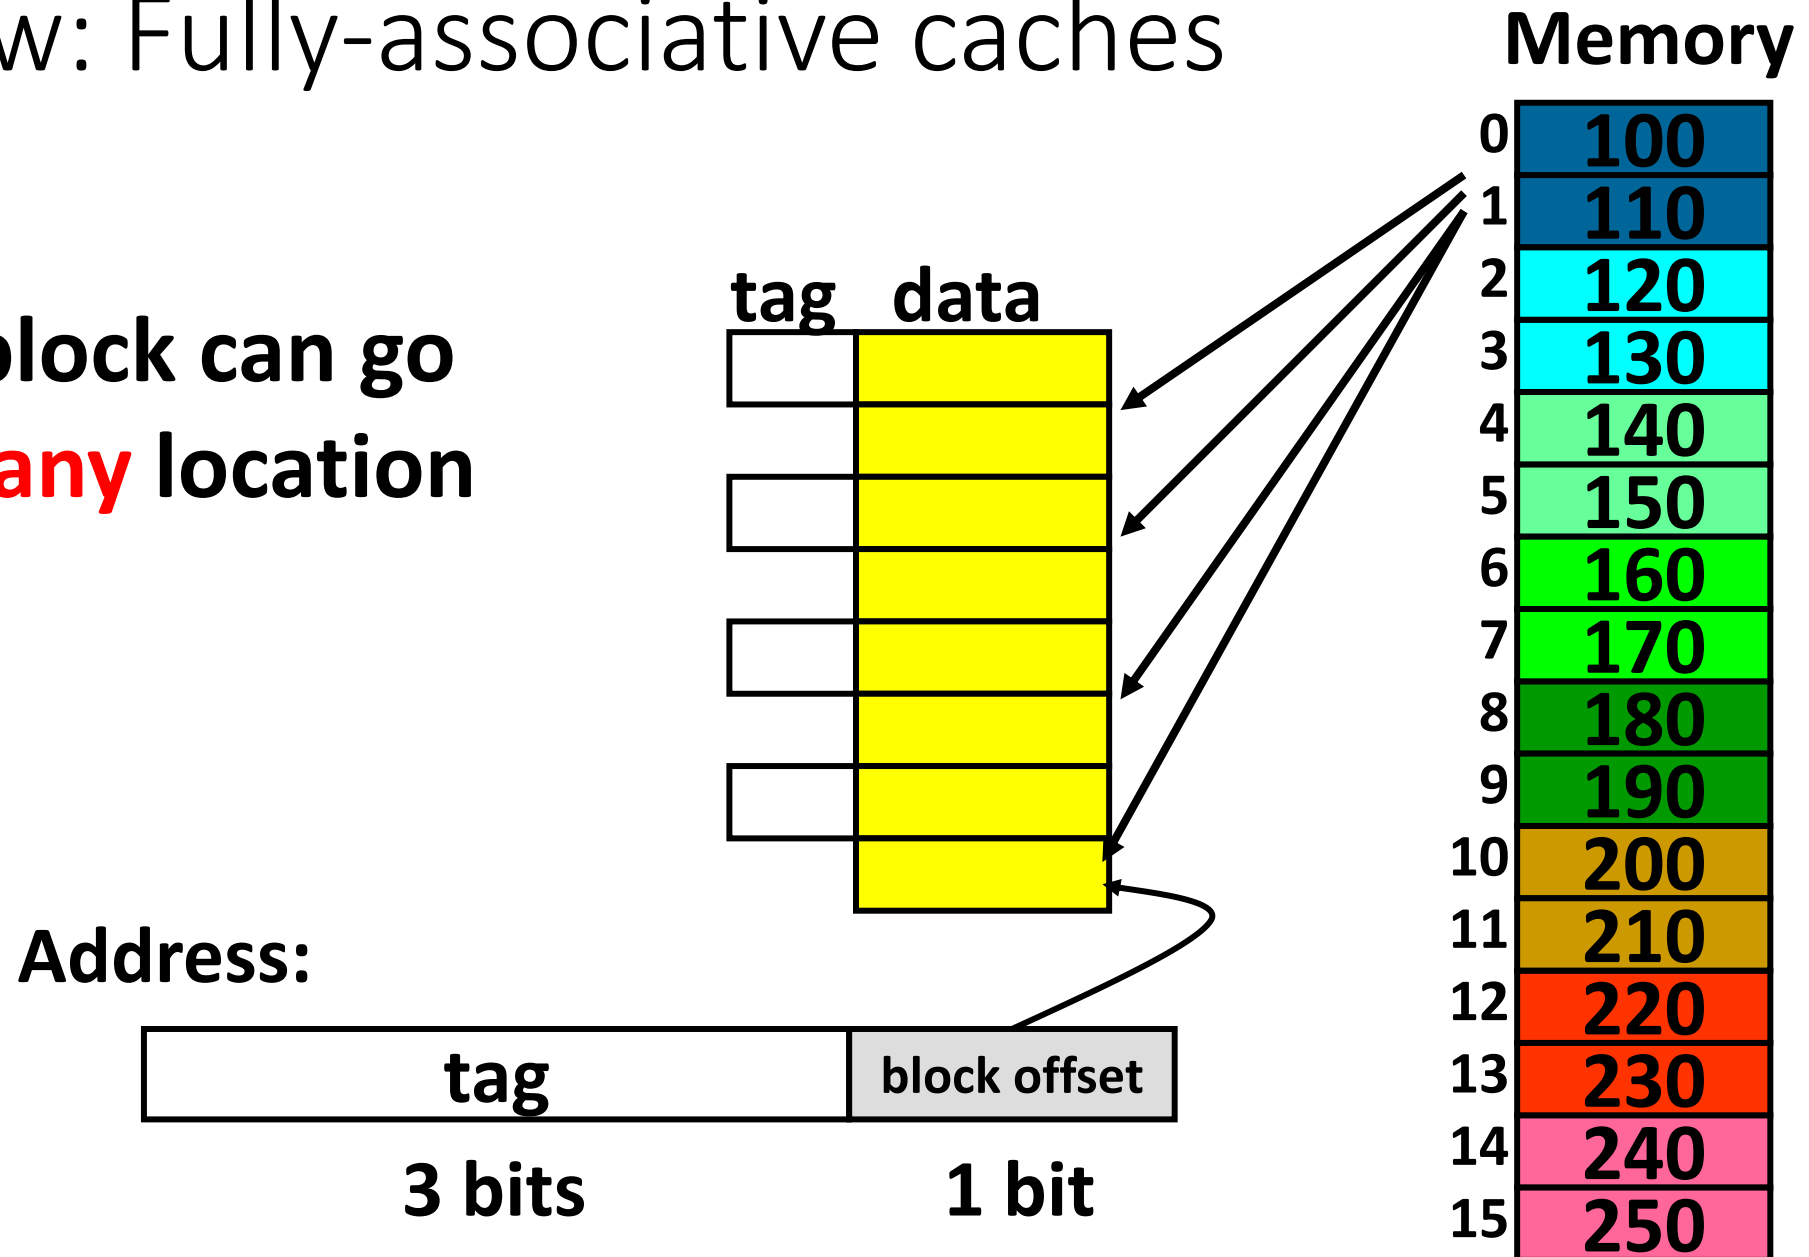

$$AMAT = 12 + (1 - 0.98) * 100 = 14 \text{ ns}$$

Agenda

- **Set-associativity overview**
- Example
- Class problem
- Integrating caches into our processor

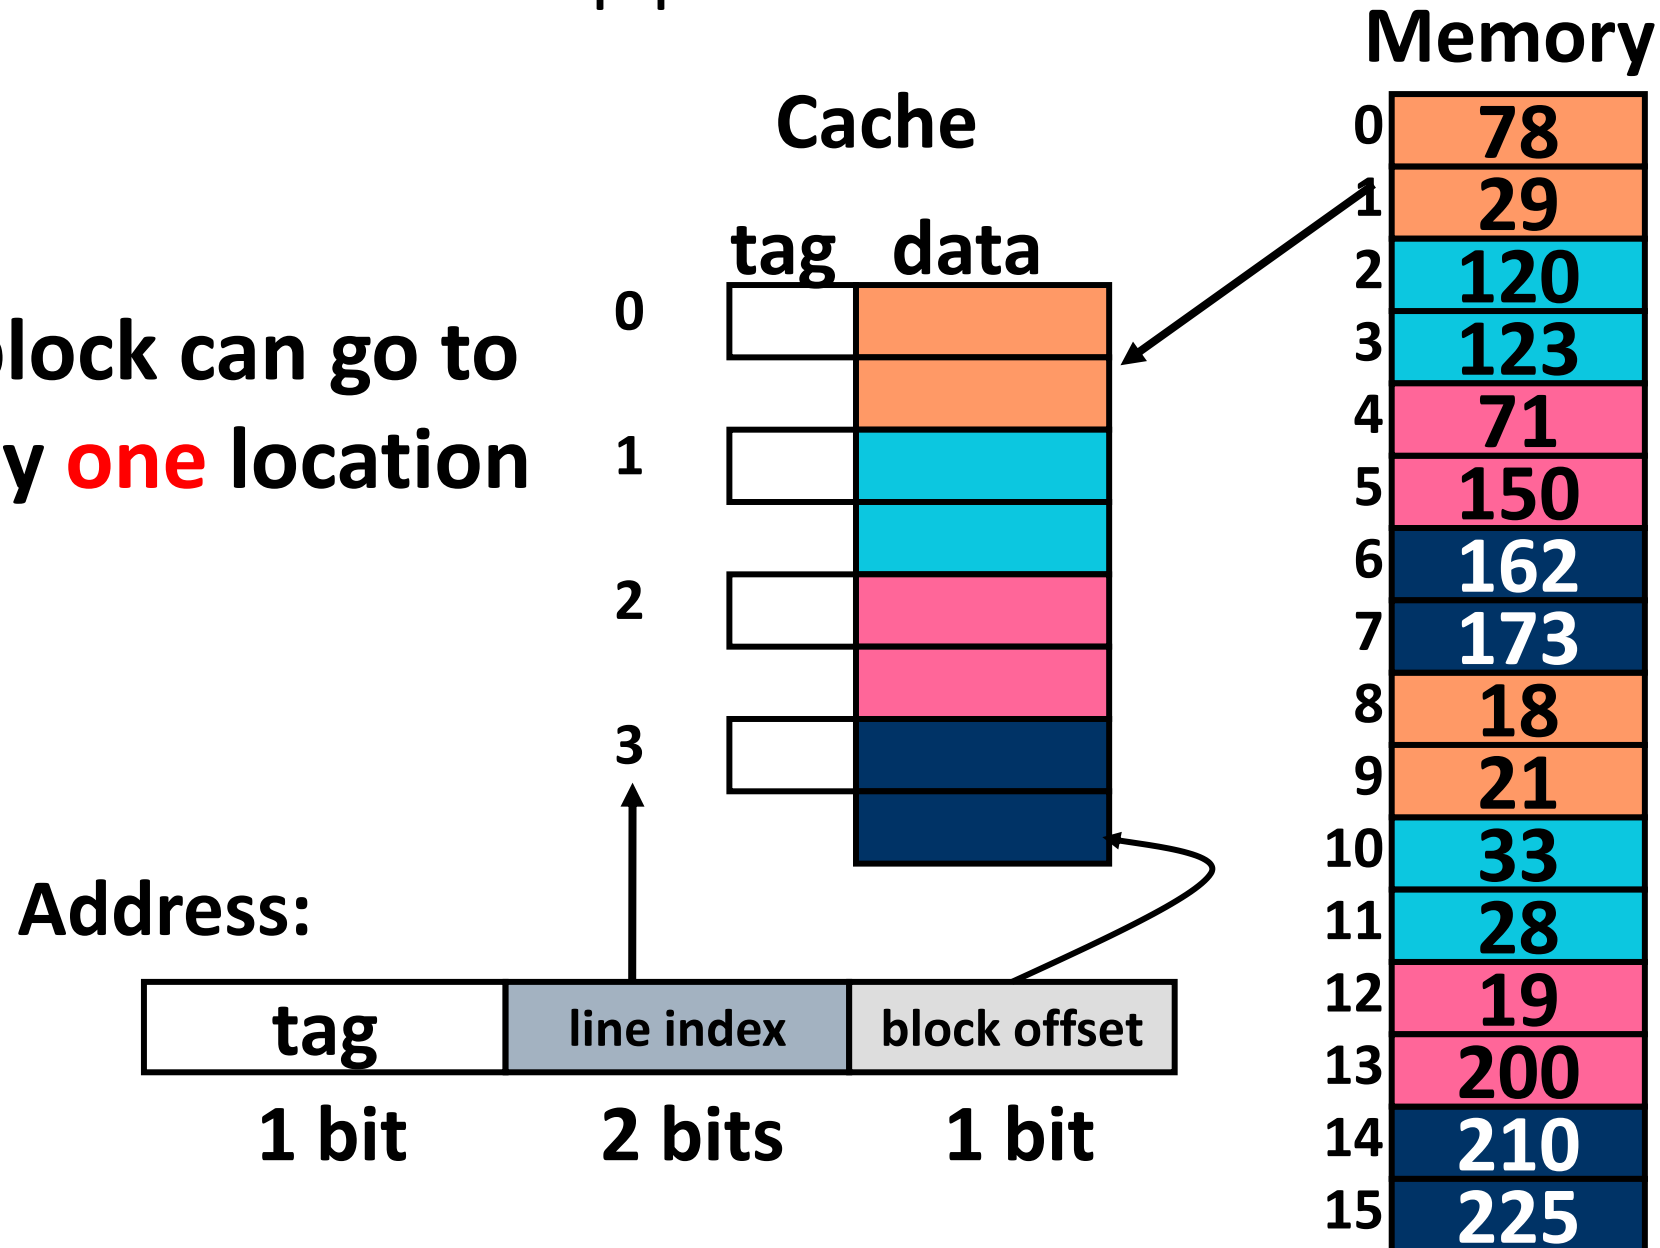

Review: Fully-associative caches

A block can go to **any** location

Review: Direct-mapped caches

A block can go to only **one** location

Generalizing caches: Motivation

- Problem: fully-associative caches give best hit rate...
 - but can only get so many entries before parallel lookups get slow
 - These days, 10s or maybe 100s of entries
- Direct-mapped caches scale up much better (100s or 1000s of entries)
 - but result in more conflicts
- Can we find a happy medium?

Set-associative caches: Idea

- Say we can scale fully associative cache to be 128 entries
 - but want to have a cache with 512 entries
- Just build $(512 / 128) = 4$ fully-associative caches
- Partition memory into 4 sets, use $\log_2(4) = 2$ bits of address to index into one of these 4 fully-associative caches
 - Then look up each tag in parallel, use LRU for eviction, etc
- Avoids (some collisions) like FU, but scales up much better
- This is a **set associative cache**
- Drawing:

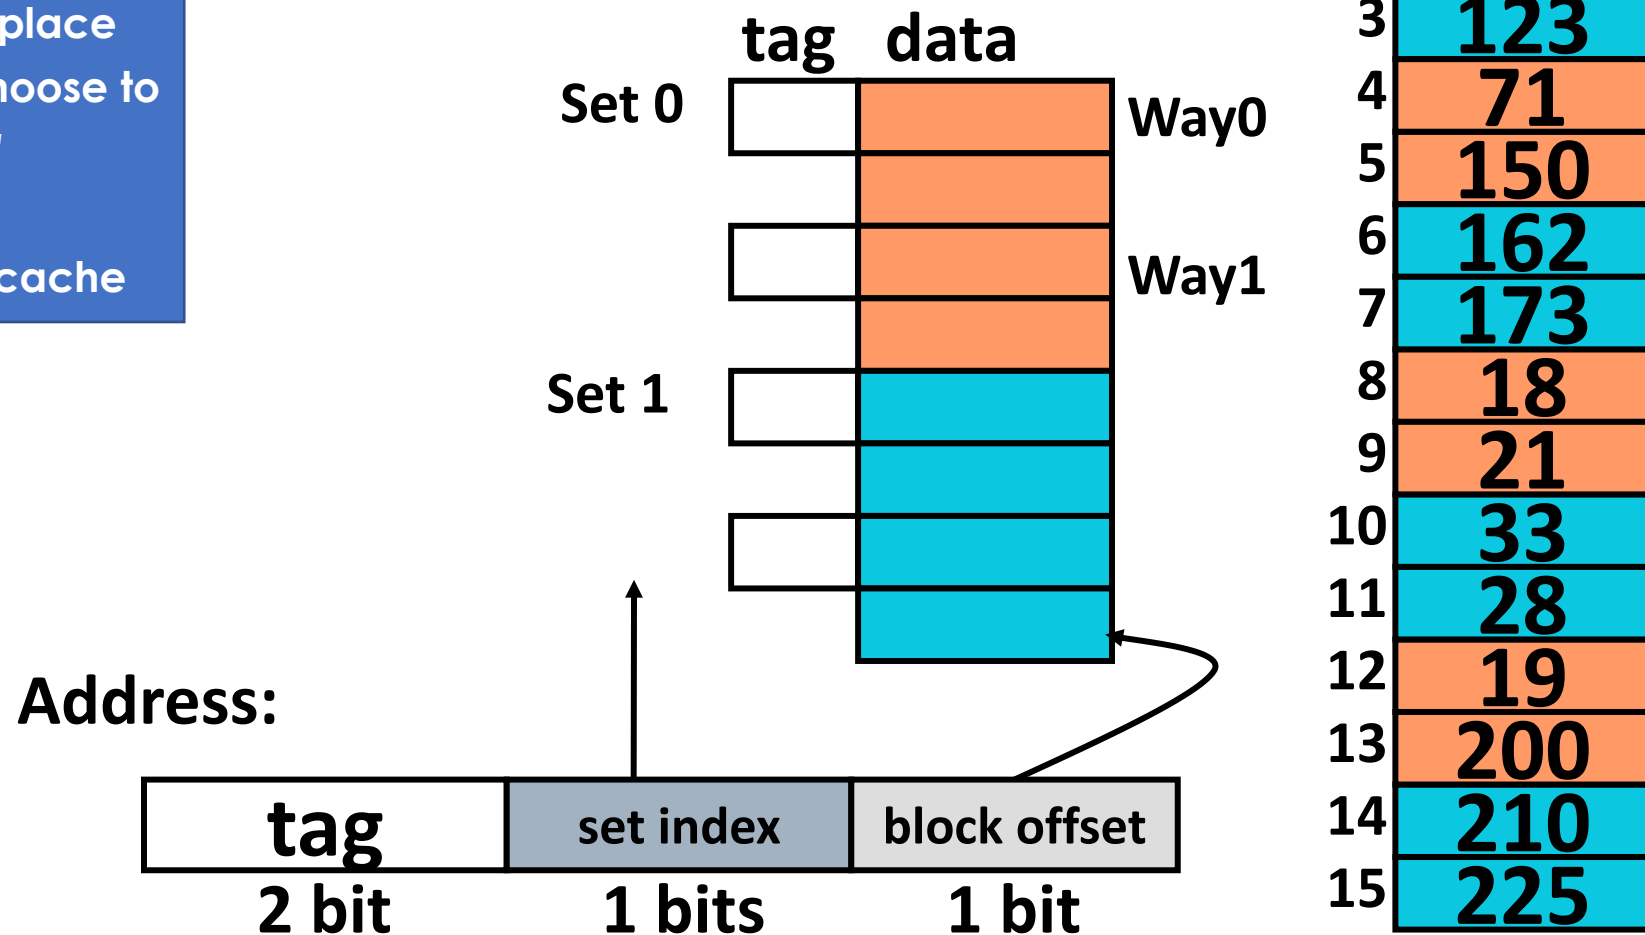

Set-associative caches

- Fully-associative & direct mapped are two extremes:
 - Slow & full placement flexibility vs fast & no placement flexibility
 - We want something in the middle
- **Set associative** caches:
 - Partition memory into regions
 - like direct mapped but fewer partitions
 - Associate a region to a **set** of cache lines
 - Check tags for all lines in a set to determine a HIT
- Treat each set like a small fully associative cache
 - LRU (or LRU-like) policy generally used

Set-associative cache

"Way" means "place hardware can choose to put data"

This is a 2-way cache

Poll: How many sets are in a direct mapped cache with N cache lines?

Calculating all the bit sizes

- For a set-associative cache:
 - # block offset bits = $\log_2(\text{block size})$
 - # set index bits = $\log_2(\text{\# of sets})$
 - # tag bits = rest of address bits
- Fully-associative
 - Special case where (\# sets) = 1
- Direct-mapped:
 - Special case where (\# sets) = (\# cache lines)

Agenda

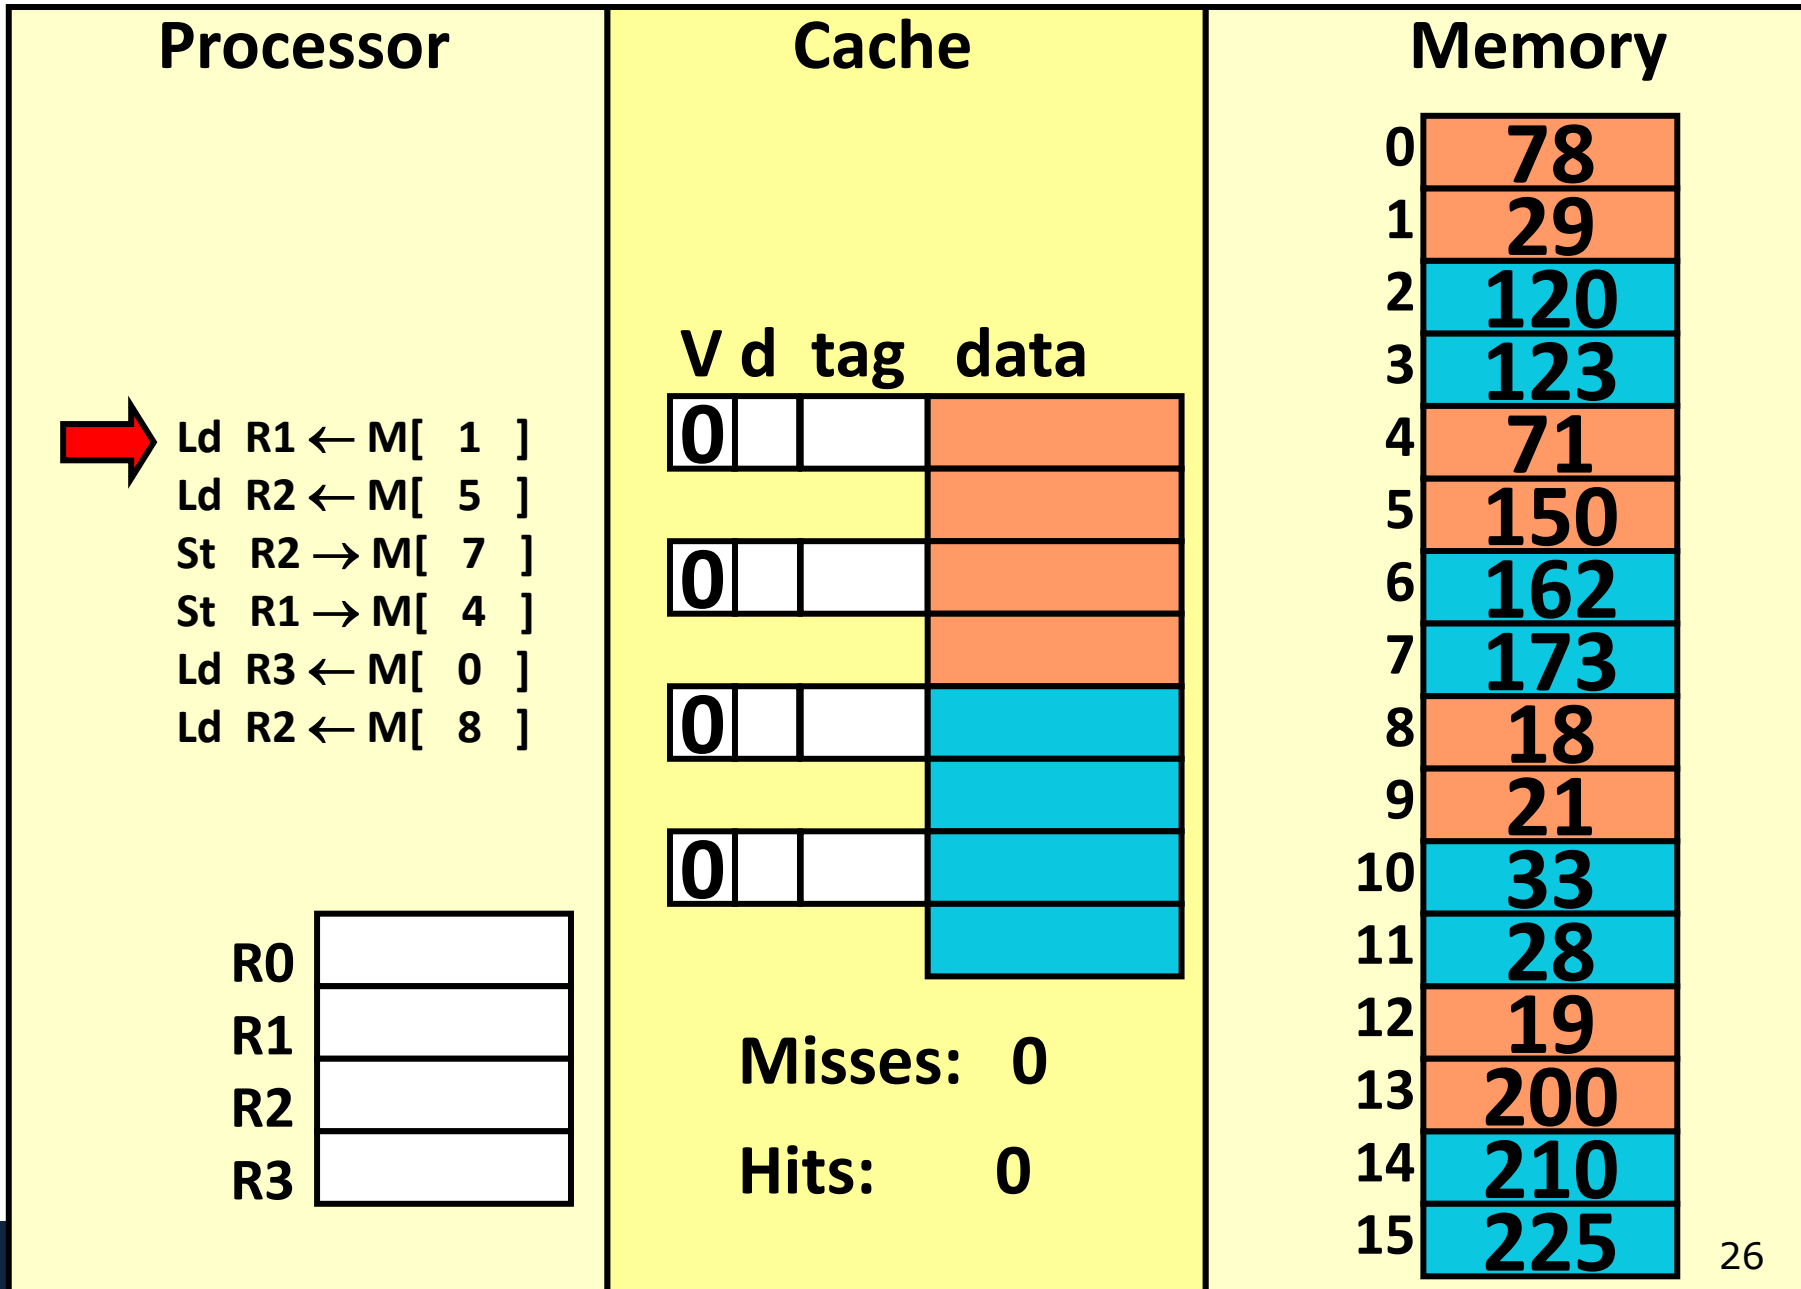

- Set-associativity overview

Agenda

- Set-associativity overview
- Example
- **Class problem**
- Integrating caches into our processor

Cache Organization Comparison

Block size = 2 bytes, total cache size = 8 bytes for all caches

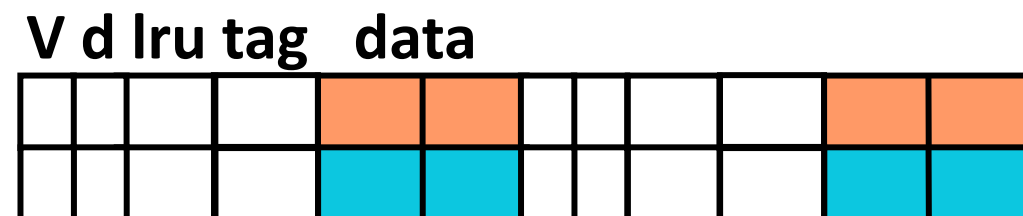

1. Fully associative (4-way associative)

2. Direct mapped

3. 2-way associative

Class Problem 1

- For a 32-bit address and 16KB cache with 64-byte blocks, show the breakdown of the address for the following cache configuration:

A) fully associative cache

B) 4-way set associative cache

C) Direct-mapped cache

Class Problem 1

- For a 32-bit address and 16KB cache with 64-byte blocks, show the breakdown of the address for the following cache configuration:

A) fully associative cache

Block Offset = $\log_2(64)=6$ bits

Tag = $32 - 6 = 26$ bits

C) Direct-mapped cache

Block Offset = 6 bits

#lines = 256 Line Index = 8 bits

Tag = $32 - 6 - 8 = 18$ bits

B) 4-way set associative cache

Block Offset = 6 bits

#sets = #lines / ways = 64

Set Index = 6 bits

Tag = $32 - 6 - 6 = 20$ bits

Agenda

- Set-associativity overview
- Example
- Class problem
- **Integrating caches into our processor**

Multi-Level Caches

- We've been considering proc -> cache -> memory
- This works well if working data set is \leq size of cache
- But if data set is a little larger than cache, performance can plummet

Multi-Level Caches

- This is the motivation of multiple levels of caches
- L1 – smallest, fastest, closest to processor
- LN – biggest, slowest, closest to memory
- Allows for gradual performance degradation as data set size increases
- 3 levels of cache is pretty common in today's systems

What about cache for instructions

- We've been focusing on caching loads and stores (i.e. data)
- Instructions should be cached as well
- We have two choices:
 1. Treat instruction fetches as normal data and allocate cache lines when fetched
 2. Create a second cache (called the **instruction cache** or **ICache**) which caches instructions only
 - More common in practice

How do you know which cache to use?

What are advantages of a separate ICache?

Integrating Caches into Pipeline

- How are caches integrated into a pipelined implementation?
 - Replace instruction memory with Icache
 - Replace data memory with Dcache
- Issues:
 - Memory accesses now have variable latency
 - Both caches may miss at the same time

Next time

- How to properly choose cache parameters?
 - Start by classifying why misses occur
